pc.egptail: The PC prior for the tail parameter in the EGP likelihood

Parametrization

This is (approximate) the PC prior for the tail parameter ξ in the EGP likelihood, where we use that the KLD to the base-model $\xi = 0$ is

$$KLD \approx \xi^2$$
.

This means that the pc-prior is

$$\pi(\xi) = \lambda \exp(-\lambda |\xi|) \frac{1}{Z}$$

where Z depends on the ξ -interval where this prior is defined (see next subsection).

Specification

This prior is to be used with family = "egp".

This prior for the hyperparameter ξ is specified in the hyper-spesification, as

hyper = list(<theta> = list(prior="pc.egptail", param=c(<lambda>, <low>, <high>))) restricted to the interval [low, high]. The default interval is [-1/2, 1/2].
